

Friday 6th January 2017

At first, this miptor is just a little dot sitting in a huge egg, but after 2 months it's ready to come out and become kangasour. It attempts to break the egg by moving around and kicking it until... Crack! A new miptor is born. As soon as it comes out of the egg, it opens its eyes and moves its head side to side to explore the world around it. When its born, its it is not the best colour, a black comma splice! mixed with orange isn't really a bright colour (but don't worry it is not staying that colour forever) luckily for the first 5 days its mother helps it out because it can't hear or smell; however it still has to eat and find water by itself for those during those 5 days.

I really enjoyed reading your life cycle. It was so interesting and very well explained.

EGG

Adulthood
20 years and
above

Life cycle
of

Kangasour

3 years old - 5 years old

After ^{three} 3 years, it begins to go hunting with its father for prey to prepare for when it's older. Instead of having milk and leaves for food, it starts to suck up ants and other minibeasts. Also, it grows spots on its back and turns from orange black and black to grey! You still might be thinking why it turns grey because grey is still a dull colour. But this ^{wondering} miptor still has a lot of changes to come its way. When it is ^{five} 5 years old, it starts making a chirping sound (like a bird) that will help it communicate when it's older.

When it finally reaches the stage of adulthood, it leaves the nest and its family to go and build its own nest. As soon as it turns eighteen, it goes out to search for a tree that's big enough to build a nest. The nest takes about 2-4 weeks to build. As soon as the nest is complete, it finds a mate to live with. ^{three to four} 3-4 weeks later, the female will lay an egg. When the miptor is born, the male will go and bring water and leaves for the baby to eat and flower petals to keep the miptor warm. kangasours can live up to 70-80 years 10-18 years old. Write in words not figures.

When its ten years old, it starts to grow more hair and gets taller and stronger so it can fight other kangasours. Now that it's older, it gets around by jumping, and it uses its hands for balancing to make sure it doesn't fall over. If its hungry, it has to go hunting by itself for prey as it is old enough to care for itself. This creature is orange in its adulthood so it starts to grow orange spots at 11-12 years old. In order to turn fully orange, it eats oranges and orange flowers. It also leaves the nest more often to get a feeling about what it's like to live on its own.

This is a well-written paragraph with good connections between sentences
